## **2022 CERN OPENLAB TECHNICAL WORKSHOP**

## Quantum machine learning questions

- Classical intractability: what useful problems can we solve on a quantum computer that we cannot on a classical computer?
- Innovation: what new algorithms can we come up with?
- Computational complexity: how can we obtain certain speedups?
- Can quantum **advantage** be proved with QML?

# Characterize Quantum Advantage

- Classical machine learning models can often compete or outperform existing quantum models even on data sets generated by quantum evolution, especially at large system sizes
- Large quantum Hilbert space in existing quantum models can result in significantly inferior prediction performance compared to classical machines: expressivity of QML hinder generalization
- We need a methodology for assessing the potential for quantum advantage in prediction on <u>learning</u> tasks
- Are there alternative research questions beyond the goal of beating classical machine learning?

## Lifecycle of a Quantum Classification Problem [6,7,8]

- Features reduction/extraction (classic step: PCA, AE, etc...)
- Data Encoding
- Feature Map / ansatz definition for kernel and variational methods
- Read Out (Different technologies, NISQ, Error...)

[6] Robust data encodings for quantum classifiers, Ryan LaRose and Brian Coyle, Phys. Rev. A 102, 032420
 [7] Quantum convolutional neural network for classical data classification, <u>https://arxiv.org/pdf/2108.00661.pdf</u>

[8] Quantum Support Vector Machines for Continuum Suppression in B Meson Decays, <u>https://arxiv.org/abs/2103.12257</u>

## Lifecycle of a Quantum Classification Problem

• Features extractions/reduction (classic step: PCA, AE, etc...)

- 1) Principal Components Analysis (PCA)
- 2) Convolutional Autoencoder
- 3) Wasserstein Variational Autoencoder
- 4) Transformers
- 5) Transfer Learning

## Lifecycle of a Quantum Classification Problem

- Features reduction/extraction (classic step: PCA, AE, etc...)
- Data Encoding  $\rightarrow$  how much is it important?

1) Amplitude Encoding

$$|\phi(x)\rangle = \frac{1}{\|x\|} \sum_{i=0}^{N} x_i |i\rangle$$

Exponential compression in number of qubits **n**qubit ∝ **O(log(N))** 

Polynomial number of gates  $n_{gate} \propto O(poly(N))$ 

## Lifecycle of a Quantum Classification Problem

- Features reduction/extraction (classic step: PCA, AE, etc...)
- **Data** Encoding → how much is it important?

→ the choice of mapping (when exact) has no impact on the learning performance of the resulting (explicit) model, ...it does impact its kernelization [4]

# **QML** implementations

### Variational algorithms - EXPLICIT

Parametric ansatz

Can use gradient-free methods or stochastic gradient-descent Data Embedding can be learned

### Kernel methods - IMPLICIT

Feature maps as quantum kernelsUse classical kernel-based trainingConvex losses, global minimumCompute pair-wise distances in N<sub>data</sub>

![](_page_9_Figure_6.jpeg)

→ What is easiest to use/define?

![](_page_9_Picture_8.jpeg)

### Data reduction - Data Encoding – Model performance (accuracy vs generalization)

DATA

#### Model

- → guidance to find a quantum advantage in ML
   → no recipe for obtaining a quantum advantage on a classical dataset [1]\_\_\_\_
- → Representer theorem: implicit models can always achieve a smaller labelling error than explicit models on the same training set [4]

[1] The Inductive Bias of Quantum Kernels - <u>https://proceedings.neurips.cc/paper/2021/file/69adc1e107f7f7d035d7baf04342e1ca-Paper.pdf</u>
 [4] Quantum Machine Learning Beyond Kernel Methods - <u>https://arxiv.org/abs/2110.13162</u>

![](_page_10_Picture_6.jpeg)

### Data reduction - Data Encoding – Model performance (accuracy vs generalization)

#### DATA

- → many relevant problems benefit from latent space connected with the theory of the specific underlying symmetry group [11]
- → identify a broad class of kernels that relate to learning problems with a particular structural aspect (group structure – i.e. discrete log) [2]
- → general method using covariant <u>kernel alignment</u> to explores a variety of fiducial states by applying a parameterised quantum circuit

#### Model

- → guidance to find a quantum advantage in ML
   → no recipe for obtaining a quantum advantage on a classical dataset. [1]
- → Representer theorem: implicit models can always achieve a smaller labelling error than explicit models on the same training set [4]

Unless we have a clear idea how the **data** generating process can be described with a quantum computer, we cannot expect an advantage by using a quantum model in place of a classical machine learning model.

![](_page_11_Picture_12.jpeg)

# **Potential Quantum Advantage**

We have to utilize the entire exponential quantum state space otherwise the quantum machine learning model could be simulated efficiently classically.

Native quantum state space to define the kernel function can fail to learn even a simple function when the full exponential quantum state space is being used.

- Reduce the dimensionality of RKHS by projection of QK:
  - to limit the expressivity
  - ➤ to construct inductive bias ——→ classically hard

→ related to the target function

![](_page_12_Picture_7.jpeg)

## A possible theoretical discriminator: The power of Data in (Q)ML algorithms [3]

![](_page_13_Figure_1.jpeg)

projected quantum kernels still use the exponentially large quantum Hilbert space for evaluation and can be hard to simulate classically

[3] The power of Data in (Q)ML algorithms - https://www.nature.com/articles/s41467-021-22539-9

![](_page_13_Picture_4.jpeg)

### A possible solution: Projected Quantum Kernel [3]

The projection allows us to reduce to a low-dimensional classical space that can generalize better

![](_page_14_Figure_2.jpeg)

Theoretically, Projected quantum kernel can learn <u>any quantum models</u> with sufficient data. It can be reconstructed by local randomized measurements using the formalism of **classical shadows.** 

[3] The power of Data in (Q)ML algorithms - https://www.nature.com/articles/s41467-021-22539-9

![](_page_14_Picture_5.jpeg)

![](_page_15_Picture_0.jpeg)

3 types of quantum machine learning models that can be formulated as linear models in quantum feature spaces:

- encoded data point is measured according to a variational observable
- weighted inner products of encoded data points are used to assign labels
- parametrized quantum circuits are universal function approximators, data- encoding layers, interlaid with variational unitaries

**EXPLICIT** a  $V(\boldsymbol{\theta})$  $U_{\phi}(\mathbf{x})$ 0 Feature encoding Variational meas. **IMPLICIT** 10) b)  $U_{\phi}(\mathbf{x})$  $U_{\star}^{\dagger}(\mathbf{x}')$ 0) Quantum kernel c) Data re-uploading circuit

[4] Quantum Machine Learning Beyond Kernel Methods - https://arxiv.org/abs/2110.13162

![](_page_15_Picture_7.jpeg)

## Quantum models comparison

- Models defined and trained variationally can exhibit a critically better generalization performance than their kernel formulations
- Explicit models is expected to terminate in *O*(*M*) optimization steps
- Implicit models can be computed using  $O(M^2)$  evaluations of inner products on a quantum computer

![](_page_16_Figure_4.jpeg)

![](_page_16_Picture_5.jpeg)

## A unified picture for EX, IM, data reuploading quantum models

- Data re-uploading circuits can be represented exactly by explicit linear models in larger feature spaces, which allows them to be reformulated as implicit kernel methods
- <u>Kernelizing a linear model</u> also has its advantages, namely generalizing its hypothesis family and turning the learning task into a convex optimization problem
- Representer theorem: implicit models can always achieve a smaller labelling error than explicit models on the same training set.
- explicit models exhibit a critically better generalization performance than their kernel formulations

→ increased expressivity can also be guaranteed to increase generalization performance??

[4] Quantum Machine Learning Beyond Kernel Methods - https://arxiv.org/abs/2110.13162

![](_page_17_Figure_7.jpeg)

PCA on 28x28 fashion-MNIST dataset, ZZ feature encoding + hardware-efficient variational unitary

## Relation between kernel and DNN in classic world [9] is true also in QC?

![](_page_19_Figure_1.jpeg)

- Every finite-width NN trained by *l*<sup>2</sup> regularized loss functions is approximately a Kernel Machine [9]
- Quantum kernel can learn arbitrarily deep quantum neural network [3]
- Gaussian kernel can learn any QNN [3]
- → Quantum ML based on kernels can be made equivalent to training an infinite depth

quantum neural network

 $\rightarrow$  Larger models has been shown empirically to

#### work better

## **Relation between kernel and DNN in classic world [9] is true also in QC?**

![](_page_20_Figure_1.jpeg)

The Neural Tangent Kernel in High Dimensions: Triple Descent and a Multi-Scale Theory of Generalization

- Trainable parameters
- The dynamics of an infinitely wide neural network (NN) trained by gradient descent can be characterized by <u>Neural</u> <u>Tangent Kernel (NTK) [5]</u>
- Neural tangent kernel shows that training neural networks with large hidden layers is equivalent to training an ML model with a particular kernel [3]
- Equivalence between NN and a broad family of  $l^2$  regularized KMs with finite-width bounds
- $\rightarrow$  every finite-width NN trained by such regularized loss functions is approximately a KM [9]
- <u>Quantum NTK</u>: deep parameterized quantum circuit whose representation power and performance are expected to be enhanced. (QNTK is not QSVM)

[3] The power of Data in (Q)ML algorithms - https://www.nature.com/articles/s41467-021-22539-9

![](_page_20_Picture_11.jpeg)

## What about barren plateau??

Noisy-induced, entanglement induced, cost function dependent...

<u>Barren plateaus</u> are large regions of the cost function's parameter space where the variance of the gradient is almost 0 - the cost function landscape is flat. This means that a variational circuit initialized in one of these areas will be untrainable using any gradient-based algorithm.

![](_page_21_Figure_3.jpeg)

![](_page_21_Figure_4.jpeg)

The variance of the gradient decreases exponentially with the number of qubits Barren plateaus in quantum neural network training landscapes, <u>https://arxiv.org/abs/1803.11173</u>

#### Avoiding barren plateaus using classical shadows - https://arxiv.org/pdf/2201.08194.pdf

#### Classical shadow estimation (VQE test)

- efficient diagnosis of the WBP both at the <u>initialization</u> step and during the <u>optimization</u> process of variational parameters
- entanglement induced BPs and BPs for local cost functions are the same
- the algorithm restarts the optimization process with a decreased value learning rate
- avoidance of BPs during the optimization using <u>quantum</u> <u>Fischer information</u>
- classical shadow protocol and the estimation of observables are stable with respect to the addition of a small but finite amount of noise

![](_page_21_Picture_13.jpeg)

31

## Conclusion

- What is the actual power of Representation learning in QML?
- Is there any potential of representation learning for Deep QNN wrt classic DNN?
- Implict vs Explicit is the same for QML and ML?

We are climbing the mountain, placing a flag for each individual contribution at the very frontier of (Q)ML
